Short Running Title: Impact of anthropogenic noise on avian fitness

S1: Predictions

Hypothesis 1: Noise negatively affects bird fitness, also increasing the opportunity for selection

- P1. We predict that experimental exposure of birds to noise will lead to reduced fitness regardless of whether direct or indirect fitness proxies are used (intercept-only mean model)
- P2. We predict that experimental exposure of birds to noise will lead to higher variance in fitness compared to control groups regardless of whether direct or indirect fitness proxies are used (intercept-only variance model)
- P3. We predict that the negative effect of noise on fitness is larger when fitness is measured directly than when it is measured indirectly (factor: Outcome_level)
- P4. We predict that the increased variance in fitness due to noise is larger when fitness is measured directly than when it is measured indirectly (factor: Outcome_level)
- P5. We predict that the negative effect of noise on fitness differs among fitness proxy categories, from larger to smaller effects being observed for: direct fitness proxies, parental investment, morphology and growth, and physiology (factor: Outcome_4)
- P6. We predict that the variance effect of noise on fitness differs among fitness proxy categories, from larger to smaller variance effects being observed for: direct fitness proxies, parental investment, morphology and growth, and physiology (factor: Outcome_4)

Hypothesis 2: Noise's negative effects on bird fitness are stronger early in life

- P7. We predict that the negative effect of noise on fitness is larger in juveniles than in adults (factor: Bird_age_category)

- P8. We predict that the negative effect of noise on fitness becomes smaller as time passes from hatching (continuous: Bird_age_2)

Hypothesis 3: Noise's negative effects on bird fitness are additive

- P9. We predict that the negative effect of noise on fitness is larger when noise exposure takes place over the whole breeding period, followed by treatments taking place post-hatching, and then pre-hatching (factor: Broadcast_period_3)
- P10. We predict that the negative effect of noise on fitness is larger, the longer the individual has been exposed to noise (continuous: Spl_time_after_noise_2)
- P11. We predict that the negative effect of noise on fitness is larger, the louder the noise treatments are (dB; continuous: Expe_noise_mean_2).
- P12. We predict that the negative effect of noise on fitness is larger, the larger the difference between the control and the noise treatments is (dB; continuous: Dif_noise_mean).

Hypothesis 4: Noise's negative effects on bird fitness differ across different methods

We will conduct several analyses on subsets of suitable data for each analysis, provided we have sufficient effect sizes per moderator level (i.e., at least 5 effect sizes per moderator level). These analyses will focus on a series of methodological differences, some of which could be considered as categories of risk of bias (more in Culina et al. 2026), between studies that are expected to lead to differences in effect sizes:

- P13. We predict that experimental designs using true and ecologically relevant noise sources (e.g., traffic, industrial) will lead to a larger negative effect on bird fitness than synthetic noise and unnatural noise sources (e.g., pink, white; factor: Noise_type_3).
- P14. For studies using true and ecologically relevant noise sources, we predict a difference in the magnitude of the negative effects of noise on bird fitness between different types of true and ecologically relevant noise sources (i.e., traffic, industrial, traffic & industrial, military; factor: Noise_type_4), but we have no specific directional expectation.
- P15. We predict a difference in the magnitude of the negative effects of noise on bird fitness between studies conducted in the wild versus in the laboratory, but we have no specific directional expectation (factor: Captive_generation_2). On the one hand, wild animals are exposed to a greater number of additional stressors (e.g., predation, parasites, disease, starvation, temperature extremes, aggression), and noise may act as the straw that breaks the camel's back, resulting in stronger effects in the wild. On the other hand, laboratory studies are often conducted with birds bred in captivity for many generations, which may have reduced their resilience through relaxed selection, potentially resulting in stronger effects in the lab. For studies conducted in the laboratory, we predict stronger negative effects of noise on bird fitness in captive-bred populations than in wild-caught populations. Beyond potentially reduced resilience due to relaxed selection, wild-caught birds are more accustomed to natural variation in ambient noise levels (e.g., wind, rain, thunderstorms) and may therefore be less physiologically stressed when exposed to increased noise in a laboratory setting.

- P16. We predict stronger negative effects of noise on bird fitness in studies that measured sound pressure levels inside versus outside the nest (factor: SPLm_pos_2). Inside-nest measurements are more biologically relevant as they better reflect the noise levels actually received by the birds. For studies using nest boxes in particular, outside measurements are likely to overestimate received noise levels, since the box itself attenuates environmental sound. As a result, outside measurements may yield an apparent mismatch between measured and received noise, potentially leading to an underestimation of effect sizes in studies relying on outside measurements.

Hypothesis 5: The literature on the noise fitness effects of birds suffers from publication biases

- P17. We predict that there is asymmetry in the funnel plot, indicating the existence of small-study effects. This is because we expect that studies on small numbers of individuals with statistically nonsignificant results tend to remain unpublished (continuous: effective_N).
- P18. We predict that evidence for a negative effect of noise on fitness has decreased since first tested. That is, that effect sizes have become smaller over time, providing evidence of a decline effect (continuous: Year.c).
- P19. We predict larger effect sizes from studies reporting data incompletely (e.g., missing effect sizes, relationships reported as simply ‘non-significant’) than from studies (presumably) reporting data in full. This test will be done at the study level (factor: ES_source_2).

S2: Search Strategy and Study Selection Details

The study selection process is shown in the PRISMA diagram in Figure S1.

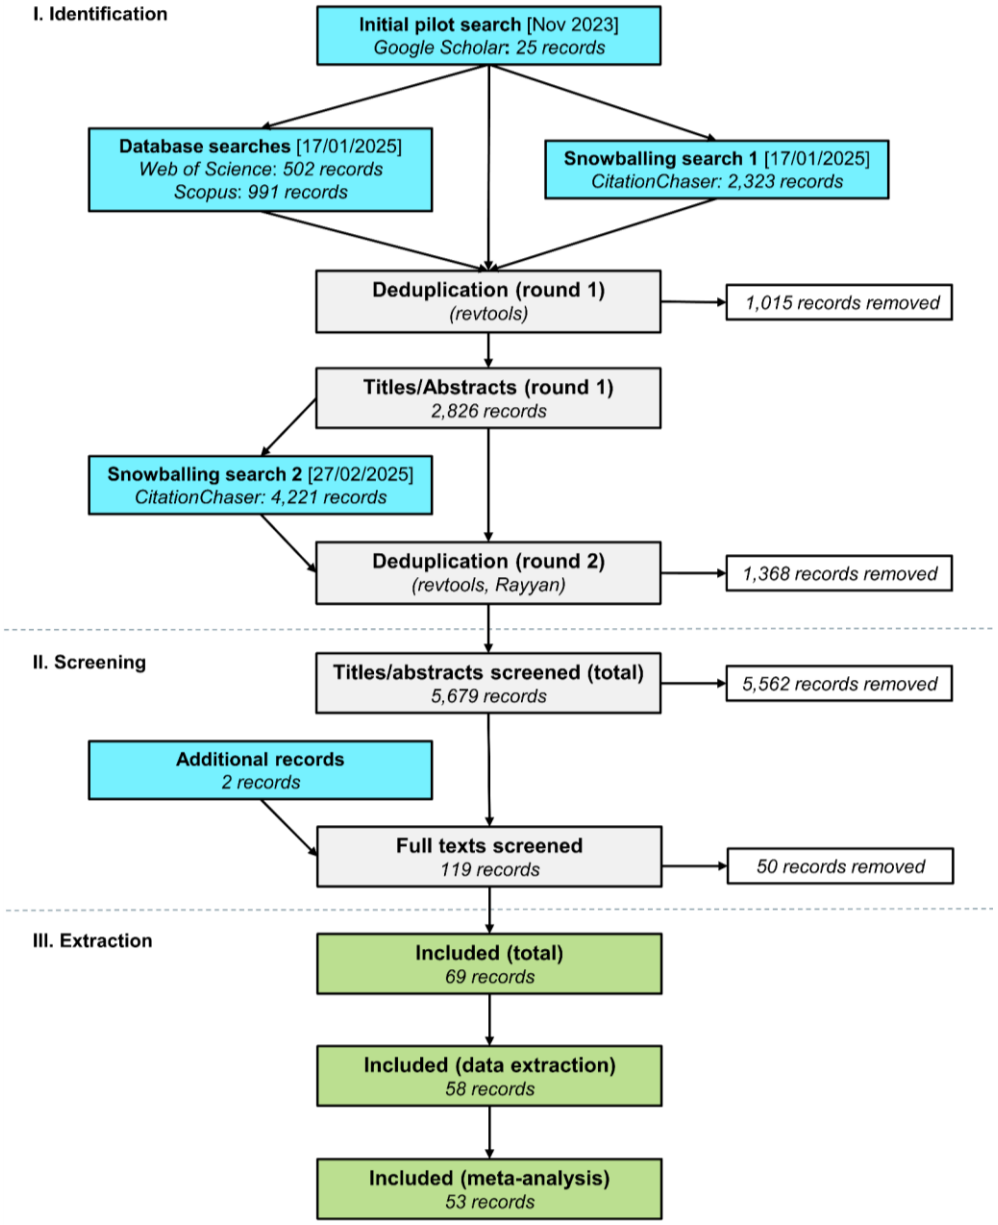

Figure S1: PRISMA diagram for the systematic review process. Initial pilot searches were conducted to identify a set of relevant studies, which was used to design database search queries. Round 1 of snowballing searches includes 1280 backwards snowballing records, and 1043 forwards snowballing records. Round 2 of snowballing was based on a set of 27 reviews and meta-analyses relevant to the research question, which were identified from within the initial set of 2,862 records. These were deduplicated to provide an additional 2,853 records for title-abstract screening. Two additional records were included during the full text screening/data extraction phases. These were both theses that were linked to other included studies. 11 studies were found to meet exclusion criteria but not included for data extraction. Data from these studies were also published in another included record, so only one study was included for extraction to avoid duplicated effect sizes. 5 additional studies were included for data extraction, but no effect sizes could be calculated from the data extracted (e.g., due to insufficient/incomplete data reporting).

Database searches were conducted in Scopus and Web of Science on the 17th of January, 2025, finding 502 and 991 records, respectively.

The following inclusion criteria were applied at the title-and-abstract screening stage.

1. Is the paper written in English, German, Spanish, Korean or Italian?
2. Does the paper report primary empirical data (i.e., not a review, meta-analysis, or purely theoretical study)?
3. Is the study species a bird, and not a farm animal in a farm/production setting?
4. Does the study assess the effect of noise specifically (i.e., not a generalised urban vs rural contrast; or ALAN)?
5. Does the study measure a measure of fitness or a fitness-related indicator (e.g., clutch size, productivity, fledgling success, recruitment rate, breeding success, longevity, body size, body mass, body condition, growth rate, etc)?
6. Does the study have a control group or explore noise gradients?

The following additional inclusion criteria were applied at the full-text screening stage.

1. Is the full text available (after thorough search, including contacting authors)?
2. Is the paper written in English, German, Spanish, Korean or Italian?
3. Is noise quantified and measured in dB or dB(A)?
4. Are noise levels manipulated experimentally?

S3: Data Extraction Details

The following variables were extracted from all studies (note that not all variables are used in the analyses, with some only being reported in the eventually provided open datasets):

- Species_latin: species latin name
- Lab_Wild: experiment in the lab or in the wild
- Captive_generation: (lab studies only) number of generations since captive (0, 1, 2, a lot)
- Latitude_N: decimal degrees
- Latitude_E: decimal degrees
- Altitude: meters above sea level (if reported)
- Season: wintering / pre-breeding /breeding / post-breeding. Refer to author's description
- Year_collection: first year of data collection
- LS_position: in nestbox / outside nestbox / distance to nestbox
- Noise_type; city / traffic / aircraft / white / other
- Group_compar_YN: is the study a group comparison (yes = 1, no = 0)
- dB_weight: e.g., A, F, C, Z
- dB_measure: e.g., Laeq or peakLA
- SPLm_pos: nestbox entrance / in nest / outside nest
- Broadcast_period: whole breeding / nest building / laying / incubation / nestling
- Ctrl_noise_min: min noise level of control group
- Ctrl_noise_max : max noise level of control group

- Ctrl_noise_mean: average noise level of control group
- Ctrl_noise_SD: standard deviation of control group
- Ctrl_noise_SE: standard error of control group
- Expe_noise_min: min noise level of experimental group
- Expe_noise_max: maximum noise level of experimental group
- Expe_noise_mean: average noise amplitude of experimental group
- Expe_noise_SD: standard deviation of experimental group
- Expe_noise_SE: standard error of experimental group
- PB_period: number of hours of noise per day / continuous
- Outcome: description of outcome measure/ fitness variable
- Outcome_unit: unit of the outcome measure/ fitness variable
- Transformation: if variable is transformed, including for modelling
- Bird_age: age of bird at measurement of outcome (in days / ad if adult / f if fledgling)
- Spl_time_after_noise: how long has the bird been exposed to noise in days
- Outcome_expected_sign_authors: direction of expected effect of noise according to authors 1 = expected increase with higher noise, -1 = expected decrease with higher noise

The following variables were also extracted as potential random effects/grouping factors:

- Lab_PI: likely primary principal investigator for study
- Pop_ID: description of specific population origin/location
- Group_ID: if several experiments are conducted with the same study using different groups of birds, give each group a unique identifier (e.g., if data is presented for 2 species, species 1 = A, species 2 = B)
- Shared_Ctrl_ID: if several treatment groups share one control group, give a unique identifier to each variable that shares a control group here (ID can be nested within Group_ID). If two rows within a Group_ID share a Shared_Ctrl_ID, the same control (or experimental) group are used across both rows.
- Shared_Ctrl_N: if several treatment groups share one control group, indicate the number of treatment groups that are sharing a control groups (note, where data includes shared experimental groups instead, or any other more complex design, this is noted here also).
- Repeated_trait_ID: if trait repeatedly measured across time, identify here (ID can be nested within Group_ID). If two rows within a Group_ID share a Repeated_trait_ID, the same variable is being measures in the same group of birds at two different time points relative to the noise treatment.

In addition to these, some additional data relating to the modelling details were also extracted, including inferential statistics (e.g., p-values, T, F, and chi-squared statistics) where they may be potentially used to calculate effect sizes in the absence of fully reported summary statistics or raw data.

A small number of studies included fully crossed treatment groups (e.g., early rearing x late rearing treatment groups). Marginalised means and errors were calculated to combine early and late treatment groups to include each treatment stage as distinct effect sizes in analysis, based on the equations in Pick et al. 2023 (as implemented in Moran et al. 2021).

S4: Supplementary Analyses

S4. Hypothesis 1, P.1: lnRR

For lnRR, birds under an experimental increase in anthropogenic noise showed an average decrease in fitness estimates, but this was not statistically significant (figure SX; lnRR = −0.013, 95% CI: [−0.032, 0.006], 95% PI: [−0.227, 0.202], p-value = 0.186, k = 501 effect sizes, n = 51 studies). Heterogeneity among effect sizes was low in absolute terms but high relative to sampling variance. Total raw heterogeneity (σ^2) was 0.012 (Q = 1834.7, p-value < 0.001), which fell in the lowest 5% of empirically derived estimates. In contrast, relative heterogeneity (I^2_{total} = 92.5%) lay between the 35th and 40th percentile, and standardised heterogeneity metrics ($CVH2_{total}$ = 73.68; $M2_{total}$ = 0.99) lay between the 90th and 95th percentile of empirically derived estimates (Yang et al. 2025).

S4. Hypotheses 1-3, P.3, P.5-P.12: lnRR

Table S1a. Meta-regression models containing categorical moderators fitted without an intercept, giving the estimate of lnRR for each level.

Model	Term	Estimate	P-value	95% CI	k	n
Fitness proxy level (H1, P3)	direct	−0.017	0.394	−0.056, 0.022	136	27
	indirect	−0.012	0.234	−0.032, 0.008	365	43

	pre-fledging	−0.018	0.181	−0.044, 0.008	158	23
Noise treatment extent (H3, P9)	post-haching	−0.005	0.801	−0.043, 0.034	151	18
	pre-hatching	−0.037	0.198	−0.093, 0.019	56	7
	unclear	**−0.110**	**0.042**	**−0.216, −0.004**	15	5
	whole-breeding	−0.007	0.656	−0.036, 0.023	252	23

Note. Values in bold indicate p < 0.05 or a 95% confidence interval (CI) not overlapping zero. k = number of effect sizes; n = number of studies; NA = not applicable.

Table S1b. Meta-regression models containing continuous moderators for lnRR.

Model	Term	Estimate	P-value	95% CI	k	n
Time after hatching (H2, P8)	intercept	−0.010	0.384	−0.033, 0.013	270	33
	Bird age 2	−0.000	0.893	−0.000, 0.000	NA	NA
Time of exposure (H3, P10-P11)	intercept	0.098	0.428	−0.145, 0.341	289	32
	Spl time after noise 2	−0.005	0.112	−0.011, 0.001	NA	NA
	Expe noise mean 2	−0.002	0.356	−0.005, 0.002	NA	NA
	Spl time after noise 2 * Expe noise mean 2	0.000	0.081	−0.000, 0.000	NA	NA
Noise treatment (H3, P12)	intercept	−0.001	0.973	−0.040, 0.039	285	25
	Dif noise mean	−0.000	0.857	−0.002, 0.002	NA	NA

Note. Values in bold indicate p < 0.05 or a 95% confidence interval (CI) not overlapping zero. k = number of effect sizes; n = number of studies.

S4. Hypothesis 1, P.2, P.4 and P.6: lnVR

For lnVR, the intercept-only meta-analysis of variance showed an average small and statistically non-significant increase in variance in fitness proxies among birds under anthropogenic noise (Hypothesis 1, P.2; figure SX; lnVR = 0.042, 95% CI: [−0.017, 0.101], 95% PI: [−0.552, 0.635], p-value = 0.166, k = 501 effect sizes, n = 51 studies). Heterogeneity among effect sizes was low to high. Total raw heterogeneity (σ^2) was 0.090 (Q = 2295.9, p-value < 0.001), and although I^2 suggested low heterogeneity (I^2_{total} = 69.4%), the other standardised heterogeneity metrics suggested high levels of heterogeneity ($CVH2_{total}$ = 52.2; $M2_{total}$ = 0.98; Yang et al. 2025).

Table S2a. Meta-regression models containing categorical moderators fitted without an intercept, giving the estimate of lnVR for each level.

Model	Term	Estimate	P-value	95% CI	k	n
Fitness proxy level (H1, P4)	direct	0.068	0.141	−0.023, 0.158	136	27
	indirect	0.033	0.299	−0.030, 0.096	365	43
Fitness proxy category (H1, P6)	fitness	0.066	0.154	−0.025, 0.157	136	27
	morphology	0.066	0.141	−0.022, 0.154	168	21
	parental investment	−0.043	0.426	−0.147, 0.062	103	19
	physiology	0.063	0.225	−0.039, 0.165	94	22

Note. Values in bold indicate p < 0.05 or a 95% confidence interval (CI) not overlapping zero. k = number of effect sizes; n = number of studies.

S4. Hypothesis 5, P.17-P.19: Publication biases

Table S3. Meta-regression models testing small-study, decline and reporting effects.

Model	Term	Estimate	P-value	95% CI	k	n
Small study effects	intercept	−0.100	0.113	−0.223, 0.024	535	53
	sqrt inv eff N	−0.057	0.785	−0.467, 0.353	NA	NA
Decline effects	intercept	**−0.114**	**0.001**	**−0.182, −0.046**	535	53
	Year c	−0.000	0.978	−0.011, 0.010	NA	NA

<<Study_ID>>
Email: <<CorrAuthEmail>>

Subject: <<AuthorsShort>> (<<Year>>) – data request for meta-analysis

Main text:

Dear <<CorrAuthName>>,
I am conducting a meta-analysis on the effects of anthropogenic noise on the fitness of birds, in collaboration with Dr Henrik Brumm (Max Planck Institute for Biological Intelligence, Germany) and Dr Alfredo Sánchez-Tójar (University of Coimbra, Portugal).

A study that you authored, <<Authors>> (<<Year>>) <<Title>>. <<*Journal*>>, contains data that would be valuable additions to this analysis, but before we can include and reference it, we require some additional information from the study.

Specifically, we would need the following information:

- <<*UnreportedDataText*>>.

Would it be possible for you to send us this information, or alternatively, the raw data, so that we can calculate these ourselves?

Your contribution will be acknowledged with a reference to your original publication in our published meta-analysis.

Your help would be greatly appreciated.
Kindly,
Nick

P.S. If you have any unpublished experimental data that could be used to test the fitness effects of anthropogenic noise on birds (means, SD or SE and sample sizes for treatments and controls), we would be very grateful if you could share it with us.
